

Package: uncorbets (via r-universe)

August 21, 2024

Type Package

Title Uncorrelated Bets via Minimum Torsion Algorithm

Version 0.1.2.9000

Description Implements Minimum Torsion for portfolio diversification
as described in Meucci, Attilio (2013)
[<doi:10.2139/ssrn.2276632>](https://doi.org/10.2139/ssrn.2276632).

<code>effective_bets</code>	<i>Effective Number of Bets</i>
-----------------------------	---------------------------------

Description

Computes the diversification probability distribution and the effective number of bets of an allocation.

Usage

```
effective_bets(b, sigma, t)
```

Arguments

<code>b</code>	A vector of exposures (allocations).
<code>sigma</code>	A $n \times n$ covariance matrix.
<code>t</code>	A $n \times n$ torsion matrix.

Value

A list of length 2 with:

- `p`: the diversification probability distribution;
- `enb`: the effective number of bets.

Examples

```
# extract the invariants from the data
set.seed(123)
log_ret <- matrix(rnorm(400), ncol = 4) / 10

# compute the covariance matrix
sigma <- stats::cov(log_ret)

# torsion
torsion_cov <- torsion(sigma = sigma, model = 'minimum-torsion', method ='exact')

# 1/N reference
b <- rep(1 / ncol(log_ret), ncol(log_ret))

# ENB
effective_bets(b = b, sigma = sigma, t = torsion_cov)
```

Description

Finds the allocation that maximizes the [effective_bets](#).

Usage

```
max_effective_bets(x0, sigma, t, tol = 1e-20, maxeval = 5000L, maxiter = 5000L)
```

Arguments

x0	A numeric vector for the search starting point. Usually the "one over n" allocation.
sigma	A $n \times n$ covariance matrix.
t	A $n \times n$ torsion matrix.
tol	An integer with the convergence tolerance.
maxeval	An integer with the maximum number of evaluations of the objective function.
maxiter	An integer with the maximum number of iterations.

Value

A list with the following components:

- weights: the optimal allocation policy
- enb: the optimal effective number of bets
- counts: the number of iterations of the objective and the gradient
- lambda_lb: the lower bound Lagrange multipliers
- lambda_ub: the upper bound Lagrange multipliers
- lambda_eq: the equality Lagrange multipliers
- gradient: the gradient of the objective function at the optimum
- hessian: hessian of the objective function at the optimum

[solnl](#)

Examples

```
# extract the invariants from the data
set.seed(123)
log_ret <- matrix(stats::rnorm(400), ncol = 4) / 10

# compute the covariance matrix
sigma <- stats::cov(log_ret)

# torsion
torsion_cov <- torsion(sigma = sigma, model = 'minimum-torsion', method = 'exact')

# 1/N reference
b <- rep(1 / ncol(log_ret), ncol(log_ret))

max_effective_bets(x0 = b, sigma = sigma, t = torsion_cov)
```

torsion

Computes the Minimum Torsion Matrix

Description

Computes the Principal Components Torsion and the Minimum Torsion for diversification analysis.

Usage

```
torsion(sigma, model = "minimum-torsion", method = "exact", max_niter = 10000L)
```

Arguments

- | | |
|-----------|---|
| sigma | A $n \times n$ covariance matrix. |
| model | One of: "pca" or "minimum-torsion". |
| method | One of: "approximate" or "exact". Only used when <code>model = "minimum-torsion"</code> . |
| max_niter | An integer with the maximum number of iterations. |

Value

A $n \times n$ torsion matrix.

Examples

```
# extract the invariants from the data
set.seed(123)
log_ret <- matrix(stats::rnorm(400), ncol = 4) / 10

# calculate the covariance matrix
sigma <- stats::cov(log_ret)

# torsion
torsion(sigma = sigma, model = 'minimum-torsion', method ='exact')
```
